

The Adobe Experience Manager (AEM) Headless JavaScript (JS) SDKs are intended to be set up and used on the **front-end (FE) side** of a project [1].

Here's a breakdown of why:

- **FE Side (Recommended):** The SDKs are libraries (e.g., `@adobe/aem-headless-client-js`, `@adobe/aem-spa-react`, `@adobe/aem-spa-project-core`) that help your front-end application (like React, Angular, or Vue) fetch and manage content from AEM's content delivery APIs [1]. They are installed via package managers like npm or yarn within your front-end project's codebase, where they handle tasks such as API requests, data mapping, and routing [1].
- **AEM Side:** The AEM side primarily involves content authoring, managing assets, defining content models (Content Fragment Models), and ensuring the content delivery APIs (e.g., GraphQL or JSON Exporter) are configured correctly and running [1]. You don't install the *client* SDKs on the AEM server itself; AEM simply acts as the back-end content repository. [🔗](#)

In short, AEM is the content source, and the JS SDKs are the tools your front-end uses to consume that content.
