

To create a left-to-right slide animation in CSS, the most performant method uses `@keyframes` and the `transform: translateX()` property. [Stack Overflow +3](#)

HTML Structure

Create an element that you want to animate. [🔗](#)

html

```
<div class="slide-element">
  This element will slide from left to right.
</div>
```

CSS Styling

Define the styles for the element and the animation using `@keyframes`. [🔗](#)

CSS

```
.slide-element {
  /* Initial state before animation starts */
  transform: translateX(-100%);
  /* Ensures smooth animation */
  transition: transform 2s ease-out;
}

/* Class to trigger the animation */
.slide-element.active {
  transform: translateX(0);
}

/* A full animation example using keyframes for continuous movement */
.animated-box {
  width: 100px;
  height: 100px;
  background-color: red;
  position: relative; /* Needed for 'left' or 'transform' to work relative to parent */
  animation-name: slideRight;
  animation-duration: 4s;
  /* Repeats the animation infinitely */
  animation-iteration-count: infinite;
  /* Makes the animation play forwards then backwards */
  animation-direction: alternate;
}
```

```
@keyframes slideRight {  
  /* Start position: completely off-screen to the left */  
  from {  
    transform: translateX(-100vw);  
  }  
  /* End position: at its original position (or specified destination) */  
  to {  
    transform: translateX(0);  
  }  
}
```

Note: Using `transform` is recommended over animating properties like `left` or `margin` for better performance. [Stack Overflow +1](#)

Explanation of Key Properties

- `@keyframes slideRight { ... }`: This rule defines the sequence of the animation, from the `from` state (0%) to the `to` state (100%).
- `transform: translateX(...)`: This property is used to move the element horizontally. A negative value moves it left, and a positive value moves it right.
- `animation-duration`: Sets how long the animation takes to complete one cycle.
- `animation-iteration-count: infinite`: Makes the animation loop continuously.
- `animation-direction: alternate`: Causes the animation to play in reverse after each forward cycle, creating a smooth back-and-forth motion. [W3Schools +4](#)

Triggering the Animation

For the first example using a transition, you would use JavaScript to add the `active` class to the element when needed (e.g., on page load or user interaction). [SitePoint +4](#)

javascript

```
// Example of how to trigger the transition using JavaScript  
window.onload = () => {  
  document.querySelector('.slide-element').classList.add('active');  
};
```

For the second example using the `.animated-box` class, the animation starts automatically when the element is rendered due to the `animation` properties being defined directly on the class. [🔗](#)
