

The code snippet `transform: none; transition: transform 225ms cubic-bezier(0, 0, 0.2, 1);` defines how an element will animate when its `transform` property changes from a non-`none` value (like `scale(1.5)` or `translateX(20px)`) back to its default state of `none`, or vice versa. [MDN Web D... +1](#)

Breakdown of the Code

- `transform: none;` : This sets the default or current state of the element to have no visual transformations applied. The element will appear in its standard position and size without any rotation, scaling, skewing, or translation.
- `transition: transform 225ms cubic-bezier(0, 0, 0.2, 1);` : This defines the animation for the `transform` property when its value changes:
 - `transform` : Specifies that the transition effect should be applied specifically to the `transform` CSS property.
 - `225ms` : Sets the duration of the transition to 225 milliseconds.
 - `cubic-bezier(0, 0, 0.2, 1)` : This is the **timing function** (or easing function) that controls the speed curve of the animation, dictating how the intermediate values are calculated during the 225ms duration.
 - The values `(0, 0, 0.2, 1)` define a custom Bézier curve. The points P0 (0,0) and P3 (1,1) are fixed as the start and end of the curve. P1 (0, 0) and P2 (0.2, 1) are control points.
 - This specific curve results in an animation that starts slowly, accelerates, and then decelerates towards the end. It is a common, smooth easing function similar to the default `ease` function in CSS. [MDN Web Docs +4](#)

How the Animation Works

The animation is **implicit**. The transition itself does not create an animation on its own; it merely specifies *how* a change in the `transform` property should be animated. [MDN Web Docs +2](#)

1. **Initial State:** The element is in a state where `transform: none;` .
2. **Trigger:** A change in state is triggered, for example, by a user hovering over the element (using the `:hover` pseudo-class) or by adding a new class via JavaScript.
3. **Final State:** The element's `transform` property is updated to a new value (e.g., `transform: scale(1.2);`).
4. **Animation:** The browser smoothly animates the element's transformation from `none` to `scale(1.2)` (or whatever the new value is) over a duration of 225ms, following the defined cubic Bézier speed curve. The change will be visually smooth rather than instantaneous. [MDN Web Docs +4](#)

The transition also works in reverse: when the trigger is removed (e.g., the user moves the mouse away), the `transform` value changes back to `none`, and the animation runs again over 225ms with the same smooth timing, returning the element to its original appearance.
