

`array.filter(Boolean)` is a JavaScript idiom used to create a new array that contains only the **truthy** values from the original array. It removes all "falsy" values—such as `null`, `undefined`, `0`, `false`, empty strings (`""`), and `NaN` —from the resulting list.  Mike Bifulco +4

How it Works

1. `filter()` iterates over every element in the array.
2. `Boolean` is a built-in constructor function that converts its argument into `true` or `false`.
3. Because `filter` only keeps items where the callback returns `true`, only elements that are "truthy" are kept.  Michael Uloth +3

It is shorthand for `array.filter(item => Boolean(item))` or `array.filter(item => !!item)`. 

Example

javascript 

```
const mixedArray = [0, 1, "Hello", "", null, undefined, "World", false];
const truthyValues = mixedArray.filter(Boolean);

// Output: [1, "Hello", "World"]
console.log(truthyValues);
```

Important Considerations

- **Removes 0:** This method removes the number `0`, which can be problematic if your array contains numbers where zero is a valid value.
- **Removes Empty Strings:** Similarly, it removes `""`.
- **Cleanliness:** While concise, it can be less readable than `array.filter(item => item !== null && item !== undefined)`.  Reddit +2

Why Use It?

It is often used to quickly clean up data fetched from APIs that might contain `null` or `undefined` entries.  DEV Community +1

- **Before:** `[1, 2, null, 3, undefined]`
- **After `filter(Boolean)`:** `[1, 2, 3]`
