

[🏠](#) > [Starting with Yarn](#) > [Installation](#)

Installation

**TIP**

The preferred way to manage Yarn is by-project and through [Corepack](#), a tool shipped by default with Node.js. Modern releases of Yarn aren't meant to be installed globally, or from npm.

1. Start by enabling [Corepack](#), if it isn't already; this will add the `yarn` binary to your PATH:

```
corepack enable
```

2. Then initialize a new project:

```
yarn init -2
```

Updating Yarn

Any time you'll want to update Yarn to the latest version, just run:

```
yarn set version stable  
yarn install
```

Yarn will then configure your project to use the most recent stable binary.

**TIP**

Yarn also frequently ships Release Candidate builds. Use `yarn set version canary` should you need a feature not released on the stable channel yet. Those builds are very stable, the only difference with the regular channel being a more staggered migration between major as we implement new breaking changes.

Installing the latest build fresh from master

You may want to test a version of Yarn so recent it hasn't been released in a Release Candidate yet, or even not merged. The following command will clone, build, and install Yarn in your project, straight from our repository:

```
yarn set version from sources
```

It accepts a `--branch` flag which you can use to test specific PRs:

```
yarn set version from sources --branch 1211
```

WARNING

Unlike the stable and canary channels, the `yarn set version from sources` command can't leverage Corepack and will need to store the Yarn binary inside the `.yarn/releases` folder and reference it from your project's `.yarnrc.yml` file.
