Creating Protected Routes in React JS With React Router V6.

The main objective of this article is to learn how to create a simple web application and protect some routes in React JS with [React Route V6](#).

React Router has transitioned from version 5 to version 6 I've been thinking about updating any articles and videos I have on this subject to show you the new ways to create protected routes in React. This is where it goes.

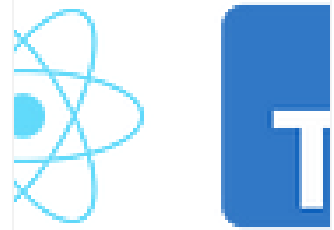

Step 1: Create a React JS application.

This article can be used to create a [new ReactJS application](#).

How to set up a React.js TypeScript project using create-react-app

This article's main objective is to create a new Create React App project with TypeScript, you can run.

medium.com

Step 2: Install the React route library.

React doesn't provide routing functionality out of the box, just like routing. A third-party library is necessary, and react-router-dom is one of the most well-known routing libraries for react JS.

```
npm install react-router-dom
```

Step 3: Create utils related to protected routes

Search

Write

In essence, this component would add functionality to the `<Route>` component by extending it, and it would then return `<Route>` with all of our parameters and additional handling instructions.

To reduce complexity, I reduced the user to a token value of true or false.

```
import { Outlet, Navigate } from 'react-router-dom'

const PrivateRoutes = () => {
  let auth = {'token': false}
  return(
    auth.token ? <Outlet/> : <Navigate to="/login"/>
  )
}

export default PrivateRoutes
```

Step 4: Utilization of private route utilities.

We would use this component in the same way we would use a `<Route>` Inside our root component `<App>`.

```
import './App.css';
import { BrowserRouter as Router, Routes, Route } from 'react-router-dom'
import Home from './pages/Home'
import Products from './pages/Products'
import Login from './pages/Login'
import PrivateRoutes from './utils/PrivateRoutes'

function App() {
  return (
    <div className="App">
      <Router>
        <Routes>
          <Route element={<PrivateRoutes />}>
            <Route element={<Home/>} path="/" exact/>
            <Route element={<Products/>} path="/products"/>
          </Route>
          <Route element={<Login/>} path="/login"/>
        </Routes>
      </Router>
    </div>
  );
}

export default App;
```

We will either render the component that was passed in or redirect a user based on the status of the `'auth.token'`.

Significant modifications have been made to React Router V6

This structure will be affected by some key changes with React Route 6.

For one, `<Redirect>` is now `<Navigate>`.

Next, `<Routes>` was added so we no longer use `<Switch>`. With this change `<Route>` must always be a child to `<Routes>` which throws out the option of being able to extend our `<Route>`. The job of the `<Routes>` component is to look through all the `<Route>` components and find a match to render to the UI. If we used `<PrivateRoutes>` here it would be ignored by `<Routes>`. So that's that.

So what do we do now?

With React Router V6 we now have a component called `<Outlet>`. The `<Outlet>` component can be used in a parent `<Route>` element to render out child elements. So the solution would be to nest private routes inside of a parent route.
